In this paper I explain why philosophy in the sense of transcendental philosophy presupposes that there is a universal logic, and why this sets a limit to some understandings of logical pluralism.

§1 Transcendental Logic and Conceptual Schemes

Kant with his introduction of transcendental philosophy as the philosophy which explores the conditions of experience in general introduced also transcendental logic as to be distinguished from formal logic. Transcendental logic in Kant’s sense is concerned as an a priori investigation with the most general rules and laws of reason. It is not set against formal logic, but contains more substantial claims than “merely” laying out the logical form of thought. The most general forms of thought, however, since they are part of the necessary conditions to apprehend objects and make judgements at all, are part of the laws of reason. Since reason is universal (i.e. all beings with reason have the same reason [as faculty]) so are these laws and the corresponding claims of transcendental philosophy. By exploring the possibility to make judgements at all transcendental logic is the foundation for any theory of truth (in general). Every specific discourse or field of empirical exploration is founded in this investigation, and it shares the most general features that characterize reason. Expressed in terms of analytical philosophy the transcendental investigation is concerned with the most general features of language (as a means of communication and representing thought). To be explained is not the framework of some individual language – be it formal or natural – but the universal frame which is presupposed by all these languages. This talk of “conceptual schemes” has been criticized by Davidson as the “third dogma of empiricism”.1 Davidson’s thesis, however, is directed against the claim that there might be several conceptual schemes which are incommensurable with respect to each other. The claim of incommensurability requires that these schemes are not translatable into each other, and this claim is incompatible with a Davidsonian theory of meaning, which starts with the concept of interpretation (or translation). A supposedly untranslatable language (incorporating a supposedly incommensurable conceptual scheme) can never be identified as language in the first place, since we start with our understanding of what a language is and identify some behaviours as possible targets of

---

translation; and at the same time we had to identify it as *language* to give the incommensurability thesis its proper content. The claim of there being several incommensurable conceptual schemes thus destroys itself. There may be beings the behaviour of which is not translatable, but once we are able to identify something as language we impose the most general features of our framework on the target. We employ here – with these means of translating and identifying – our *universal* (or transcendental) *framework of language*. Thus within our kind of linguistic life form the concept of language (and what more specific general features go with it) is one and not many. The many natural language share the features that the universalist tries to identify. Formal languages – that usually abstract from some dimension of language, usually pragmatics as a whole – share some of the features that define, for example, what it takes for an expression to be composed or to have meaning. Davidson’s complain about talking of several conceptual schemes should so be read as highlighting the fact that we already have taken our stances within our conceptual scheme. There has to be something that is shared by the many languages. The problem is to identify these features. The task of universal linguistic philosophy is to identify the features of the transcendental frame of language. It might not be much, and it might be quite formal or parameter ridden what is universal in this sense, but it has to be there.

Transcendental philosophy thus is universal. And it should be. Philosophy cannot restrict itself to non-universal languages. The language of philosophy has to be semantically closed. Philosophy does not want to deal only with the structure or conditions of talking in some specific language or languages of some kind, but aims at a theory of the basic structures and conditions of having a language *in general*.

This requires the corresponding resources to express the universal claims. There must not be a hierarchy of languages so that we always talk in a *last* meta-language the semantic properties of which cannot be made clear, except in a further turn of the screw (a new meta-language ...). Universal theories of meaning, truth, knowledge etc. were not to have if we can talk only from some meta-language "down" to some distinct object-language. A general statement like

\[1] \text{Knowledge is true belief.}\]

would be not well-formed. But these are the very theories that philosophy is after. And notwithstanding their lip-service to hierarchy solutions of the antinomies most philosophers propose their general theories of meaning, truth, belief, reference, knowledge etc. They are right to do the latter, since we have such universal concepts.

There seems to be no crucial difference between formal languages and natural languages with respect to the properties being of interest here (i.e. semantic and structural properties), al-
though formal languages have no native speakers, mostly no pragmatics, no socio-linguistics – and so on.

We can investigate and formalize the logical structures of any natural languages. That is one of the central tenets of logic and formalization. We not only talk about properties of all (natural) languages, it seems even incoherent whether there could be two completely incommensurable languages. Such a system could never be identified as a language at all.

There are several logics. This is, however, hardly evidence against universalism: Often standard first order logic and set theory are taken as the meta-language to prove theorems about the logic in question; sometimes – as it should be in intuitionism or dialetheism – the meta-language is taken to be the same logic as the one introduced or explained; but in all cases the logic and its formalisms are argued for in natural language texts. Natural language turns out to be the last meta-language, that meta-language in which the most basic formalisms of some other meta-language were introduced. And natural language turns out to be the universal meta-language in that all the formal constructions and sentences of some new system can be translated (read) as ordinary sentences with some formal regimentation. There is no extraordinary special or deviant new logic which can say something that we cannot say in (some) natural language. Natural language thus contains the understandability of all these systems. What structures are responsible for this may the task of advanced transcendental philosophy to find out. And we have to make a further distinction between those languages which are possible as such and those which are feasible in the sense of being the medium of communication and representation of embodied, finite, interacting social beings like us intervening in and adapting to a law governed environment.

Our concept of language, therefore, involves unity and universality. There has to be a set of properties defining what a language is. These properties are preserved in change or translation, they are exploited to establish correspondences.

Elucidating these properties and making them explicit from our intuitive understanding of language(s) is the traditional understanding of (transcendental) philosophy (of language). Without semantic closure we would not be able to elucidate a concept that we seem to have!

Transcendental philosophy in face of the paradoxes coming with semantic closure becomes a version of dialetheism: There are true contradictions within the universal framework and logic has to be adapted accordingly.²

§2 Universal Logic

Corresponding to this universal scope of its investigations transcendental philosophy needs the logical means to speak universally. Thus transcendental philosophy needs a universal logic.

There are two readings of having a universal logic: weak universal logic and strong universal logic. A universal logic might be universal as a paraconsistent logic, i.e. in all fields in which we need a paraconsistent logic this logic can be employed and gives acceptable results. This may be called the weak universalist program. One may take the weak universalist program as being extremely cautious: One takes one’s favoured paraconsistent logics – and sticks to it in all contexts. Since this paraconsistent logic can deal with contradictory contexts it can deal with any context, so it really is universally applicable. The problem with this extreme caution is that one loses all otherwise available consequences in consistent contexts. Therefore one rather tried to distinguish the type of context one is reasoning in. In praxis this meant that we employ standard First Order Logic for all non-semantic or non-antinomic contexts and switch to paraconsistency only in our formalization of complete semantics (or, maybe, set theory).

Or a truly universal logic can be employed everywhere, supposedly containing a way to distinguish consistent from inconsistent contexts, without loss of proper logical power in comparison to FOL. This may be called the strong universalist program. In case philosophy contains consistent contexts and uses arguments valid only in consistent contexts it seems to need to follow a strong universalist program.

Both the Logics of Formal Inconsistency (LFI) approach in paraconsistent logic and Adaptive Logics follow the idea to be able within the system used to distinguish contexts of a stronger logic (usually FOL) and contexts for a paraconsistent logic. The way they do it is completely different, however.

In the LFI-approach the distinction what kind of context we have has to be given beforehand; only given the corresponding knowledge can we choose the appropriate formalization (i.e. use °A or not). In Adaptive Logics we mark the supposition that some formula has to be consistent, a supposition that may be revised in the process of reasoning; no prior knowledge about the consistency behaviour of a context is required. Some rules like Disjunctive Syllogism [¬A, A∨B→B] and ex contradictione quodlibet [¬A, A→B], and all derived rules depending on them, have to be restricted. Restriction means here that they are only used if the on the left hand side of the application no contradiction is involved. Without adaptivity we had to reason using some paraconsistent logic in all contexts which we suppose to contain contradictions. Given that quite a lot of standard logic is missing [including contraposition,
transitivity (of identity) etc.] that is a severe restriction. We cannot capture a lot of (harmless) consequences in that field then. Philosophy as that area of universal talk about semantics and epistemology would have to use such a restricted logic. It is questionable how many of its theses and arguments could really (i.e. without hidden recourse to standard logic) be expressed. Adaptivity, on the other hand, makes clear that reasoning from the present contradictions is rather the exception than the rule.

[Proponents of the corresponding camps within paraconsistency (like Diderik Batens) are, however, outspoken logical particularists, i.e. they propose that one chooses a logic given a particular task or topic at hand. So one may try a little mixing of ideas.3]

That we are in the vicinity of some really universal logical principle may be revealed by our failure to negate this principle in asserting something. Logical principles built into our faculty of logic and language used in communication will be principle that can only be attempted to negate by uttering some statement which is the formal negation of this principle but in which case we have an immediate and obvious performative contradiction between the content of the statement and the presuppositions of the act of assertion going on at that time. So to say “I do believe A \( \land \) B, but I do not believe A.” is self-destructive in that the “but” works logically as an “\( \land \)” and so the statement makes sense only if both conjuncts uttered are taken to be in force by the assertion, which is what the assertion overtly tries to negate.

§3 What about Pluralism in Logic?

Is universal logic thus understood incompatible with logical pluralism?

This depends on what logical pluralism is taken to assert.

- If pluralism just means that there are several logical systems, and one may use some specific system of some specific purpose this is compatible with the claim that there is the logic of universal discourse. The many logics may be used where appropriate, and their mere existence has no deeper philosophical impact than the observation that given a specific purpose at hand one may abstract from a lot of things.

- If pluralism means that there cannot be a logic of universal discourse this thesis is rejected by transcendental philosophy (by the arguments hinted at above). If philosophy has a universal assignments and one does not want to slip into murmurings about the ineffability of our linguistic faculties there has to be a system that represents what languages have to have in common to be translatable and to be used as medium of thought and interaction.

---

3 Cf. the system UL4 in: Bremer, [footnote 2].
If pluralism means, for example, that there are different “negations” it is confused about meaning. Some so called “deviant logic” should not be understood as showing that what, for example, Negation is is up for grasp, or that there is no real negation. We are free to invent new symbols for new negation related functions, and if careless may even take established symbols for our now used negation related function. But by this we neither bring a new negation into the world or bring standard negation out of it. There just are a set of truth functional options in the vicinity of standard negation. Deciding to call some other of these “negation” using “¬” does not change Negation, it changes the meaning of some symbols. There is no “truth by convention” in the sense that merely stipulating some axioms makes the involved symbols true of the world; giving badly enough chosen axioms these may not be true of the world, or at least not in the intended sense. So one cannot change Negation by fiat. What Negation really is – on the other hand – may be a tough question. Maybe some of the non-standard connectives is closer to Negation in Universal Logic. The whole discussion about negation, however, presupposes that there is some central truth function these different logics try to pin down.

If pluralism means that there cannot be a unique system of universal logic (that is the one best system of doing universal logic) this seems to be a version of relativism (and fares no better than relativism fares with respect to any other scientific field).

One understanding of Carnap’s slogan “to plan languages” and his “principle of tolerance” may see Carnap as advocating complete instrumentalism and relativism with respect to linguistic frameworks. Extreme conventionalism fails in fixing the set of (proper) logical truths: If a semantic idealist (claiming that truth can be generated by convention) believes that any convention can do, he is subject to the famous “tonk”-counterexample of absurd rules for introducing and eliminating logical connectives. An “or”-like introduction rule with an “and”-like elimination-rule yields “A∧¬A” even for consistent statements A. Non-logical truth – at least in part related to the idea of correspondence – is not generated by convention either. Extreme conventionalism or extreme logical pluralism as a version of semantic idealism is incompatible with even mild versions of realism. There is more to the “old” Frege/Russell-theory that the laws of logic correspond to the most general structures of the world. Comparing different ways to express universal logics is thus not idle. One of them has to be the best one. Even if all questions that we can put are questions internal to our conceptual scheme that does not mean that they are trivially answerable. The main problem of transcendental philosophy is

that this very framework is not explicitly given. Thus we lack the representation of the framework in respect to which all structural questions are decided. The exploration of transcendental philosophy set out to reconstruct this frame. Comparing several of these (partial) reconstructions we may improve the picture, and by improving the picture reject some universal logics as less appropriate renderings of our linguistic faculties. Philosophical arguments concerning formal ontology and logic might be read then as arguments to the appropriate representation of the transcendental frame.

§4 Comments on some Recent Proposals of Pluralism

J.C. Beall, Greg Restall, Gert-Jan Lokhorst and Achille Varzi have defended their version(s) of logical pluralism.\(^5\)

Beall and Restall define being a pluralist about logical consequences as ‘you need only hold that there is more than “one true logic” ’; pluralism in this sense is clearly compatible with universalism and having logics for more specific fields or tasks. Saying that there are ‘equally good logics’ amounts to no more than saying that there are equally good tools, but a hammer and a spade being both good tools, does not make the hammer fit for digging. Their second definition of pluralism says ‘you can hold that two different logics \(L\) and \(L'\) are both accurate and systematic accounts of (different specialisations of) the one notion of logical consequence’. Is this pluralism in a relevant sense? Of course there may be partial representations of \(x\) both focussing on some specific aspect, but this does not make them incompatible as long as one does not take a partial description for a complete one. (This is true also in the case of empirical description: Even if there are more comprehensive [scientific] descriptions available it is – at that level of description – not wrong to say that the cat is on the mat.) This does not rule out that there is one and only one accurate comprehensive description, and with respect to logic it does not rule out that there is one and only one best representation of logical consequence in general. As logics are used to reconstruct arguments the principle of shallow analysis demands that we bring to light no more logical structure than is needed to give the argument a form in which it is valid (i.e. in the case of a successful reconstruction of a correct argument). Since not every time an argument is valid its validity depends on it form in modal logic we may abstract from modal logical form in these cases, but this does not make the option to give a more complete formalization into a case of logical pluralism in any interesting

An interesting case of logical pluralism would only be given if with respect to the same concepts (like quantification or modalities) different proposals are presented for the logic of such a given specific concept. Beall and Restall seem even to acknowledge this in case of the many model logics, about which they say that ‘once you are specific about what your logic is meant to do, there is scope for genuine disagreement’. That is true if the two systems are proposed as comprehensive renderings of the area of logic in question. The disagreement may not be so easy to resolve in general logic as it is in some highly constrained area of applied logic, but as there is only one true comprehensive description of the world, there may be only one comprehensive universal logic. However our logical faculties work and how difficult it turns out to capture them in a formal specification, they are “just there”, and one (universal) logical system is the way of representing them, whether we get to know it or not.

Later Restall went beyond this claiming that with respect to the partial explications of logical consequence ‘there is no further fact of the matter’ whether some argument is valid or not; this may be the road down to relativism. The examples chosen (arguments classically valid, but not valid in some paraconsistent logics) are unconvincing, since the universal logic in store may be an adaptive logic that can incorporate both perspectives. What is right about the examples is that only those examples matter in which one and the same pattern is once considered valid and once not; the mere fact that an argument (i.e. a piece of text to be formalized) turns out to be correct only relative to one logic and not relative to the other is irrelevant, since the correctness of an argument is typically taken to be established by the fact that there is one sound pattern of reasoning in which it can be transformed by formalization, there has not to be a pattern for any arbitrary argument in any logic whatsoever.

Varzi tries to defend relativism in a more extreme Carnapian sense by pointing out that the distinction between logical constants (drawn in standard logic and semantics) and extra-logical terms ‘is ultimately ungrounded’. That is true. In fact that is what the transcendental philosophers claims: The scope of transcendental logic exceeds that of formal logic in that there are more concepts involved in the structural a priori rules of reason that those explicated in formal logic. Conceding this, however, does not mean that all ways of carving up the logical and the extra-logical are equally good.

Lokhorst tries to revive the thesis that people from different cultures reason with different logics. If this is meant in the strong sense that there is not a transcendental frame which is able to put the two natural language reasoning systems into correspondence it is refuted by being a version of the incommensurability thesis (see §1). If this just meant that some people may use
a system that corresponds to a subsystem of the system that some other people use, this is again no interesting case for pluralism just as incomplete knowledge is no argument for (epistemic) relativism. That one may construct strange formal systems that are incompatible with some basic tautologies (like $A \supset A$) shows no more than that one may construct strange theories about the world that are incompatible with some basic assumptions about our universe (e.g. that the universe is extended).\(^6\) To claim that some people (i.e. people like humans we know living on a planet like ours) may use such a logic is *not really conceivable*, just as no engineer can work on the premise that the universe is not extended in space.

So it seems that logical pluralism is either a version of relativistic semantic idealism – a position no one should easily associate herself with, not the last, since it is wrong – or it is only an appeal to the fruitfulness of a division of labour in logic research – that is a helpful attitude to stop useless controversies, but it has little epistemological impact beyond what we already know about partial descriptions in other fields of inquiry.

---

\(^6\) One may even argue that those systems that just convert some features of our logic (like switching *true* and *false* as the designated truth value) are permuted variants of it, and thus no counterexample at all.
